Clinical image description

A 05-year-old girl, from a non-consanguineous marriage, born by cesarean section with the use of forceps.

She has a familial atopy: Allergic rhinitis in father and sister due to dust mites and pollen and a history of cervical poly lymphadenopathy 05 months before the onset of symptoms with spontaneous regression, the viral origin was suspected but no viral serology was done.

The history of the disease dates back to the age of 4.5 years with the appearance of erythematous lesions after eating some foods (initially popcorn and ice cream) affecting only the face, spontaneously resolving after a few seconds. The evolution was marked by an increase in the frequency of the appearance of lesions, especially after the consumption of acidic, cold, sweet and solid foods (Toothpaste, bread and cold water).
