Clinical image description

A 67-year-old male patient who was circumcised was admitted to our national institute of oncology with a scrotum mass. His medical history revealed no multiple sexual partners or sexually transmitted disease, or previous surgery. He was on regular medical treatment for cardiopathy disease. Physical examination revealed an 8 cm budding ulcerative mass located in the left testicle extended to the base of the penis Figure. Their examination had shown also, multiple warts scattered across

the lower abdomen; in the hypogastric region, and the right and left iliac fossae (Figure). Inguinal region examination showed bilateral palpable lymphadenopathy. A skin biopsy of the testicle was performed. Pathological examination results reported moderately differentiated, infiltrating, and non-keratinizing epidermoid carcinoma. CT scan of the chest and abdomen did not reveal distant metastases. The patient is undergoing neoadjuvant chemotherapy between radiotherapy.
